## **ABSTRACT**

PURPOSE: To produce a diffraction grating capable of diffracting the light in the wide range of wavelength by laminating >=2 kinds of polymer layers having a different refractive index so that the thicknesses of the layers are varied.

CONSTITUTION: High-refractive-index polymer layers 1, 3 and 5 and low-refractive-index polymer layers 2, 4 and 6 are alternately laminated by coating to form a layer consisting of >=2 kinds of polymers having a different refractive index. The wavelength of the diffracted light is controlled to 800-2000nm by varying the thicknesses of the layers, and a heat reflecting film transmitting visible light and reflecting heat rays is obtained in this case. The laminate is applicable to a color filter for reflecting a light of specified wavelength in the visible region, a UV cutoff film, etc.
